
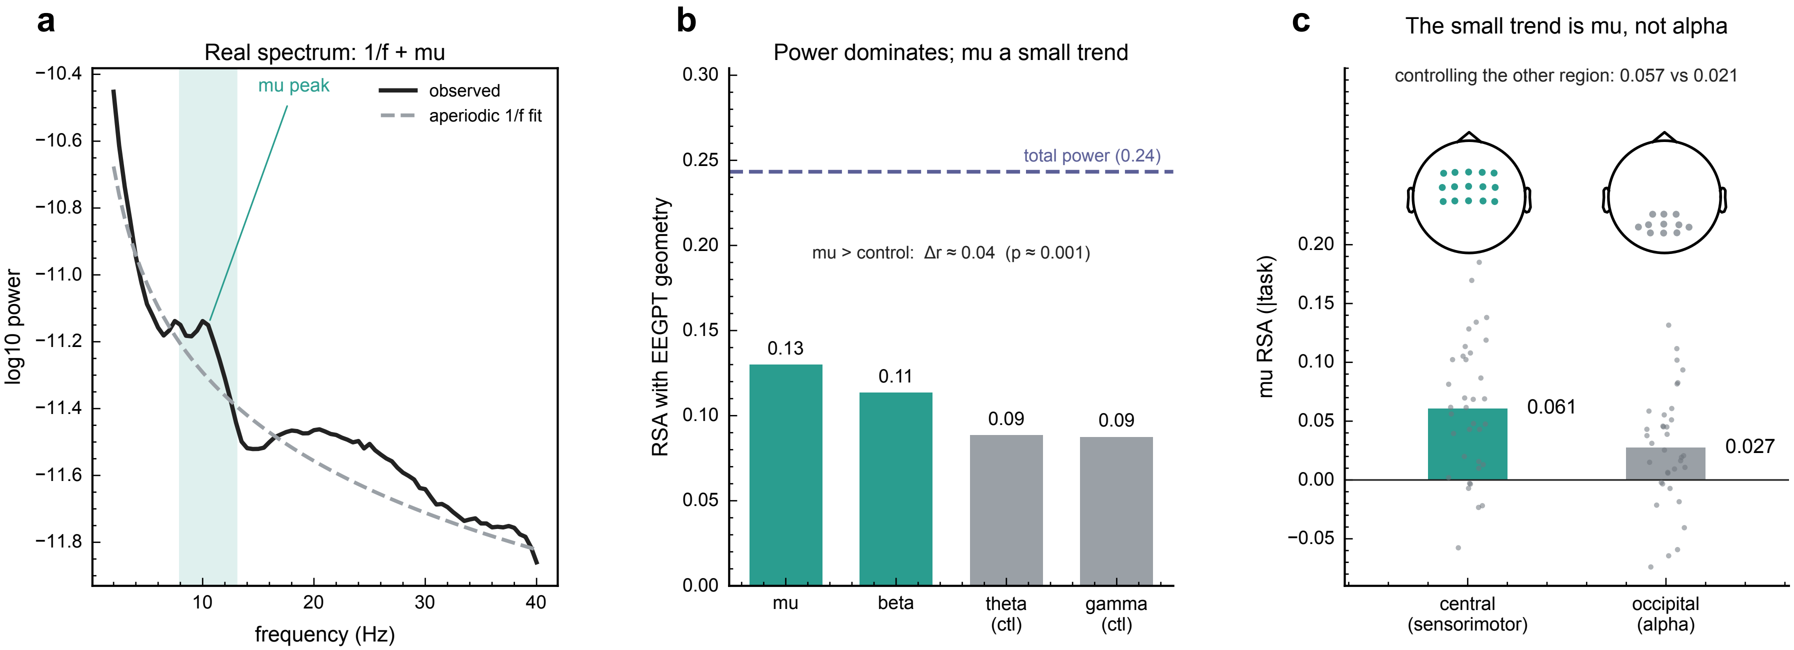

Figure 1. Auditing EEGPT on motor imagery (PhysioNet, n = 35 subjects, 2891 cued 4 s trials). (a) Grand-average sensorimotor spectrum with its fitted aperiodic 1/f component and the mu peak above it. (b) The embedding geometry tracks aggregate total power (dashed, r ≈ 0.24) far more than any aperiodic-adjusted band; mu sits only ≈ 0.04 above the non-motor controls. (c) Mu and posterior alpha share the 8-13 Hz band, so the trend is tested against location: alignment is much stronger over central than occipital electrodes and survives partialling out the other region (dots are subjects). Electrode regions are channel space, not source localization.
